

Homework 5

- 1.** Let $(Z_t)_{t \in \mathbb{R}}$ be a Gaussian process with autocovariance

$$r(\tau) = \mathbb{E}(Z_t Z_{t+\tau}) = (1 + |\tau|)^{-\gamma}$$

for $\gamma > 0$. For two correlated $N(0, 1)$ random variables X, Y with $\mathbb{E}(XY) = \rho$ it can be shown that $\mathbb{E}(\operatorname{sgn}(X)\operatorname{sgn}(Y)) = \frac{2}{\pi} \arcsin \rho$. Let $\varepsilon_t = \operatorname{sgn}(Z_t)$. Compute the asymptotic behaviour of $\mathbb{E}(\varepsilon_t \varepsilon_{t+\tau})$ as $\tau \rightarrow \infty$. Explain how you would simulate ε .

Solution.

$$\mathbb{E}(\varepsilon_t \varepsilon_{t+\tau}) = \frac{2}{\pi} \arcsin \mathbb{E}(Z_t Z_{t+\tau}).$$

But $\arcsin x = x + O(x^3)$ as $x \rightarrow 0$, so

$$\mathbb{E}(\varepsilon_t \varepsilon_{t+\tau}) \sim \frac{2}{\pi} \mathbb{E}(Z_t Z_{t+\tau}) = \frac{2}{\pi} (1 + |\tau|)^{-\gamma} \sim \frac{2}{\pi} |\tau|^{-\gamma}.$$

We can use the Cholesky method to simulate Z and hence ε , and the covariance matrix $R_{i,j} = \mathbb{E}(X_{t_i} X_{t_j}) = r(|t_i - t_j|)$ is constant along diagonals (we call this a Toeplitz matrix), so it is much faster to compute as it only has n distinct entries.

- 2.** Let X denote a Lévy process and assume X_t has a density for simplicity. Then there exist two non-negative, non-decreasing Lévy processes (L^{-1}, H) for which

$$\mathbb{E}(e^{-qL_t^{-1}-zH_t}) = e^{-\kappa(q,z)t} \tag{1}$$

for $q, z > 0$, where

$$\kappa(q, z) = \exp\left(\int_0^\infty \int_0^\infty (e^{-s} - e^{-qs-zx}) \frac{1}{s} \mathbb{P}(X_s \in dx) ds\right).$$

Take the limit as $q \rightarrow 0$ in (1) with $z = 0$. What happens if X is Brownian motion?

Solution.

$$\lim_{q \rightarrow 0} \mathbb{E}(e^{-qL_t^{-1}}) = \mathbb{E}(1_{L_t^{-1} < \infty}) = \mathbb{P}(L_t^{-1} < \infty) = e^{-t\kappa(0,0)}$$

where

$$\kappa(0,0) = \exp\left(\int_0^\infty \int_0^\infty (e^{-s} - 1) \frac{1}{s} \mathbb{P}(X_s \in dx) ds\right) = \exp\left(-\int_0^\infty \frac{1}{s} (1 - e^{-s}) \mathbb{P}(X_s > 0) ds\right).$$

If X is Brownian motion then $\mathbb{P}(X_s > 0) = \frac{1}{2}$ is independent of s , so the integral simplifies to $\frac{1}{2} \int_0^\infty \frac{1}{s} (1 - e^{-s}) ds = \infty$, so $\kappa(0,0) = 0$, and $\mathbb{P}(L_t^{-1} < \infty) = 1$.
