

# Homework 6

1. From a famous result called the **reflection principle**, it is known that  $\mathbb{P}(M_t > b) = 2\mathbb{P}(W_t > b)$ , where  $M_t = \max_{0 \leq s \leq t} W_s$ . Can Brownian motion remain non-negative over a non-zero interval  $[0, \delta]$ ? Compute the cdf of  $m_t = \min_{0 \leq s \leq t} W_s$ .

**Solution.**  $\mathbb{P}(M_t > 0) = 1$ , so (setting  $t = \delta$ ) we see that  $W$  sets a new max over  $[0, \delta]$ . But by symmetry,  $\mathbb{P}(m_t < 0) = 1$  as well, so  $W$  sets a new minimum as well a.s., so the claim is false. For the final part, let  $b \leq 0$ . Then using that  $m_t \sim -M_t$ , we see that

$$\mathbb{P}(m_t \leq b) = \mathbb{P}(-M_t \leq b) = \mathbb{P}(M_t \geq -b) = 2\mathbb{P}(W_t \geq -b) = 2\Phi^c\left(\frac{|b|}{\sqrt{t}}\right).$$

2. Let  $\theta_t = \max\{s : W_s = M_t\}$  denote the **last time** that  $W$  achieved its current maximum value  $M_t$ . The cdf of  $\theta_t$  at  $s$  is given by

$$F(s) = \mathbb{P}(\theta_t \leq s) = \frac{2}{\pi} \arcsin \frac{\sqrt{s}}{\sqrt{t}}$$

for  $t$  fixed (this is known as the **arcsine rule**), proof not asked for here. Explain how we can simulate  $\theta_t$ .

**Solution.** We use the usual  $F^{-1}(U)$  method from the first lecture where  $U \sim U[0, 1]$ . In this case

$$F^{-1}(U) = (\sin(\frac{\pi U}{2})\sqrt{t})^2 = \sin^2(\frac{\pi U}{2})t$$

and note that  $F^{-1} : [0, 1] \rightarrow [0, t]$ .

**Remark 0.1** The density of  $\theta_t$  is  $\frac{d}{ds}F(s) = \frac{1}{\pi\sqrt{s(t-s)}}$  for  $0 < s < t$ , which is a special case of a beta distribution.

3. Explain how to simulate two random variables  $X$  and  $Y$  with joint density  $f(x, y)$ .

**Solution.** Simulate  $X$  in the usual way as  $F_X^{-1}(U)$ . Simulate  $Y$  using  $F_{Y|X}^{-1}(U_2)$  where  $U_1, U_2$  are i.i.d.  $U[0, 1]$ , where  $F_{Y|X}$  is the conditional cdf of  $Y$  given  $X$ . To compute  $F_{Y|X}$ , recall that conditional density of  $Y$  given  $X$  is

$$f(y|x) = \frac{f(x, y)}{p(x)}$$

where  $p(x)$  is marginal density of  $X$ . The conditional cdf is then given by  $F(y|x) = \int_{-\infty}^y f(u|x)du$ .

4. Compute the asymptotic distribution of  $\Pi_t^n = \sum_{i=0}^{n-1} (W_{\frac{(i+1)t}{n}} - W_{\frac{it}{n}})^2$  as  $n \rightarrow \infty$ .

**Solution.** Let  $\Delta W_i = W_{i\Delta t} - W_{(i-1)\Delta t}$  where  $\Delta t = \frac{t}{n}$ . Then from the Brownian motion chapter we saw that

$$\Pi_t^n = \sum_{i=0}^{n-1} (W_{\frac{(i+1)t}{n}} - W_{\frac{it}{n}})^2 = \sum_{i=1}^n (\Delta W_i)^2 \sim \sum_{i=1}^n (\sqrt{\Delta t} Z_i)^2 = \Delta t \sum_{i=1}^n Z_i^2 = \frac{t}{n} \sum_{i=1}^n Z_i^2$$

where  $Z_1, Z_2, \dots$  is an i.i.d sequence of  $N(0, 1)$  random variables. Then from the Strong Law of Large Numbers (SLLN),  $\Pi_1^n \rightarrow t$  a.s. as  $n \rightarrow \infty$ . Moreover, we also know that

$$\text{Var}\left(\sum_{i=1}^n Z_i^2\right) = \sum_{i=1}^n \text{Var}(Z_i^2) = 2n$$

since  $\mathbb{E}((Z_i^2)^2) = \mathbb{E}(Z_i^4) = 3$  and  $\mathbb{E}(Z_i^2) = 1$ , so  $\text{Var}(Z_i^2) = 3 - 1 = 2$ . Then

$$\text{Var}\left(\sum_{i=1}^n (\Delta W_i)^2\right) = \text{Var}\left(\sum_{i=1}^n (\sqrt{\Delta t} Z_i)^2\right) = n \text{Var}(\Delta t Z_i^2) = n(\Delta t)^2 \cdot 2 = 2n\left(\frac{t}{n}\right)^2 = \frac{2t^2}{n}.$$

Moreover

$$\sqrt{n} \left( \sum_{i=1}^n (\Delta W_i)^2 - t \right) \sim \sqrt{n} \left( \sum_{i=1}^n \Delta t Z_i^2 - t \right) = t\sqrt{n} \left( \frac{1}{n} \sum_{i=1}^n Z_i^2 - 1 \right) \quad (1)$$

and from the **Central Limit Theorem** the right hand side tends weakly to a  $N(0, 2t^2)$  random variable. Hence for  $n$  large we can approximately say that  $\sum_{i=1}^n (\Delta W_i)^2 - t \sim \frac{1}{\sqrt{n}} N(0, 2t^2)$

**5.** Recall from Hwk 5 that a symmetric  $\alpha$ -stable process  $X$  with parameters  $\alpha \in (0, 2]$ ,  $\sigma > 0$  is a generalization of Brownian motion, which has i.i.d. increments like Brownian motion and  $\mathbb{E}(e^{iu(X_t - X_s)}|X_s) = \mathbb{E}(e^{iu(X_t - X_s)}) = e^{-(t-s)\sigma^\alpha|u|^\alpha}$  for  $u \in \mathbb{R}$ ,  $0 \leq s \leq t$ , and we assume  $X_0 = 0$ . Explain how to estimate  $(\alpha, \sigma)$  using **linear regression** if we have observations of  $X_1, X_2, \dots, X_n$ .

**Solution.** Let  $\Delta X_i = X_i - X_{i-1}$  for  $i = 1 \dots n$ ; then the  $\Delta X_i$ 's are i.i.d. and  $\mathbb{E}(e^{iu\Delta X_i}) = |\mathbb{E}(e^{iu\Delta X_i})| = e^{-\sigma^\alpha|u|^\alpha}$  for  $u \in \mathbb{R}$ . Moreover if we define  $\hat{\phi}_n(u) = \frac{1}{n} \sum_{i=1}^n e^{iu\Delta X_i}$ , then  $|\mathbb{E}(\hat{\phi}_n(u))| = |\mathbb{E}(e^{iu\Delta X_1})| = e^{-\sigma^\alpha|u|^\alpha}$  for all  $i = 1 \dots n$ , and taking logs we see that

$$\log(-\log|\mathbb{E}(\hat{\phi}_n(u))|) = \alpha(\log \sigma + \log|u|).$$

Then to estimate  $(\alpha, \sigma)$ , we remove the expectation from the LHS and perform linear regression on  $f(u) := \log(-\log|\hat{\phi}_n(u)|)$  versus  $\log|u|$  on a grid of  $u$ -values  $(u_j)_{j=1 \dots m}$ , which minimizes  $\sum_{j=1}^m (y_j - a - bx_j)^2$  with  $x_j = \log|u_j|$  and  $y_j = f(u_j)$ . Then the slope will then be  $b = \hat{\alpha}$  and the intercept will be  $a = \hat{\alpha} \log \hat{\sigma}$ .

**6. Fundamental Theorem of Asset Pricing.** Consider a general stock price process  $S$  of the form

$$dS_t = \mu_t dt + \sigma_t dW_t$$

with  $r = 0$  where  $\mu_t$  and  $\sigma_t$  are  $\mathcal{F}_t^W$ -adapted and  $\int_0^T (|\mu_u| + \sigma_u^2) du < \infty$  a.s. Assume there exists another probability measure  $\mathbb{Q}$  **equivalent to**  $\mathbb{P}$  such that  $S$  is a martingale under  $\mathbb{Q}$ . Show there is no-arbitrage in the model under this general condition.

**Solution.** Let  $V_t = \int_0^t \phi_u dS_u$  with  $\mathbb{E}^{\mathbb{Q}}(\int_0^T \phi_u^2 \sigma_u^2 du) < \infty$ . Assume the strategy is self-financing and starts from zero initial wealth, so  $V_0 = 0$ . There is an arbitrage if there exists an  $\mathcal{F}_t$ -adapted process  $\phi$  such that  $\mathbb{P}(V_T \geq 0) = 1$  and  $\mathbb{P}(V_T > 0) > 0$ . Since  $\mathbb{P}$  and  $\mathbb{Q}$  are equivalent we also have  $\mathbb{Q}(V_T \geq 0) = 1$  and  $\mathbb{Q}(V_T > 0) > 0$ , which implies that  $\mathbb{E}^{\mathbb{Q}}(V_T) > 0$ .

But  $S$  is a  $\mathbb{Q}$ -martingale, and (for an admissible trading strategy  $\phi$ )  $V_t = \int_0^t \phi_u dS_u$  is also a  $\mathbb{Q}$ -martingale with  $V_0 = 0$ . Hence  $\mathbb{E}^{\mathbb{Q}}(V_T) = V_0 = 0$ , so  $V_T = 0$   $\mathbb{Q}$ -a.s. This contradicts  $\mathbb{Q}(V_T > 0) > 0$ , so no such arbitrage strategy can exist.

**Remark 0.2** The density  $p(x)$  of  $\chi = \sum_{i=1}^n Z_i^2$  is  $\chi^2$  with  $n$  degrees of freedom, and has the explicit formula  $p(x) = \frac{1}{2^{n/2}\Gamma(\frac{1}{2}n)}x^{\frac{1}{2}n-1}e^{-\frac{1}{2}x}$  for  $x > 0$ .

**7.** A Generalized Brownian bridge  $\hat{B}$  on  $[0, T]$  is a Brownian motion  $B$  conditioned to end at  $b$  at time  $T$ . Compute the density of  $\hat{B}_t$  for  $t \in [0, 1]$ .

**Solution.** Let  $p_t(x) = \frac{1}{\sqrt{2\pi t}}e^{-\frac{x^2}{2t}}$  denote the density of Brownian motion at time  $t$ . Then from Bayes rule for conditional densities

$$\mathbb{P}(\hat{B}_t \in dx) = \frac{\mathbb{P}(B_t \in dx, B_T \in db)}{\mathbb{P}(B_T \in db)} = \frac{p_t(x) p_{T-t}(b-x)}{p_T(b)} dx.$$

If we tidy this expression up further, we recover a Normal density for  $\hat{B}_t$ .

**8.** From e.g. Hwk4 q2, we know that

$$\mathbb{P}(W_t \in dx, M_t < b, m_t > a) = \frac{2}{b-a} \sum_{n=1}^{\infty} e^{-\lambda_n t} \sin\left(\frac{n\pi(x-a)}{b-a}\right) \sin\left(\frac{n\pi(0-a)}{b-a}\right) dx \quad (2)$$

for  $a < x < b$ , where  $\lambda_n = \frac{n^2\pi^2}{2(b-a)^2}$ , and  $M_t$  and  $m_t$  are the running max and min processes of  $W$ . Use this to explicitly compute the **conditional cdf** of the **two-sided maximum**  $R_t := \max_{0 \leq s \leq t} |W_s|$  of  $W$  at time  $t$ , **given that**  $W_t = 0$ .

**Solution.** Setting  $b = r$  and  $a = -r$  we did in Hwk2 q2,  $b - a = 2r$  and we can re-write (2) as

$$\mathbb{P}(W_t \in dx, M_t < r, m_t > -r) = \mathbb{P}(W_t \in dx, R_t < r) = \frac{1}{r} \sum_{n=1}^{\infty} e^{-\lambda_n t} \sin\left(\frac{n\pi(x+r)}{2r}\right) \sin\left(\frac{n\pi(0+r)}{2r}\right) dx$$

for  $x \in (-r, r)$ , where  $\lambda_n = \frac{n^2\pi^2}{8r^2}$ . Then since  $\{M_t < r\} \cup \{m_t > -r\} = \{R_t < r\}$ , using Bayes' formula and setting  $x = 0$  in (3), we see that

$$\mathbb{P}(R_t < r | W_t = 0) = \frac{\mathbb{P}(R_t < r, W_t \in dx)}{\mathbb{P}(W_t \in dx)}|_{x=0} = \frac{\frac{1}{r} \sum_{n=1}^{\infty} e^{-\lambda_n t} \sin\left(\frac{1}{2}n\pi\right)^2}{\frac{1}{\sqrt{2\pi t}}} = \frac{\sqrt{2\pi t}}{r} \sum_{k=1}^{\infty} e^{-\lambda_{2k-1} t} \quad (3)$$

where we have set  $n = 2k - 1$  for  $k \in \mathbb{N}$ , and used that  $\sin(\frac{1}{2}n\pi)$  vanishes for  $n$  even (see final plot below).

**9.** Let  $X_1, \dots, X_n$  denote a sequence of i.i.d. random variables with common cdf  $F$ , and let  $F_n(x) = \frac{1}{n} \sum_{i=1}^n 1_{X_i \leq x}$  denote the **empirical cdf**.

It can be shown that

$$\hat{B}_t^{(n)} = \sqrt{n} (F_n(F^{-1}(t)) - t)$$

(defined for  $t \in [0, 1]$ ) tends to a (zero-mean) Gaussian process  $\hat{B}$  with covariance function  $R(s, t) = \mathbb{E}(\hat{B}_s \hat{B}_t) = s(1-t)$  (for  $0 \leq s \leq t \leq 1$ ) as  $n \rightarrow \infty$ . Recall we have seen the Gaussian process with this covariance function before in Hwk 1 which can be realized as  $\hat{B}_t = (1-t)W_{\frac{t}{1-t}}$  where  $W$  is a standard BM. We don't prove it here, but one can show that  $\hat{B}$  can also be realized as a Brownian motion conditioned to be zero at time 1 (i.e. the same process considered in q7+8 when the final time  $T = 1$ ).

If the observed value of  $D_n := \max_{t \in [0, 1]} |\hat{B}_t^{(n)}| = R$  for a sequence of observations  $X_1, \dots, X_n$  with  $n$  large, explain how we can test the null hypothesis  $H_0$  that the sequence  $(X_i)$  is i.i.d. with cdf  $F$ , at the 5% significance level.

**Solution.** If  $H_0$  is true, then from the stated asymptotic result,  $D_n$  has approximately the same distribution as  $\max_{t \in [0, 1]} |\hat{B}_t|$ , which is the same as the two-sided maximum  $R_t$  in Eq (3) in q8 if we set  $t = 1$  there. Hence if  $\mathbb{P}(R_1 > R) < .05$ , we reject  $H_0$ . This is known as the **Kolmogorov–Smirnov** goodness-of-fit test, which is a famous statistical test, which can be computed in Python using `scipy.stats.kstest(Z, 'norm')`, or `stats.ks_1samp(Z1, stats.norm.cdf, method='exact')` which uses the exact distribution of  $D_n$ .

**10.** Let  $X_i \sim N(0, 1)$  be i.i.d., and  $\bar{m}_{3,n} = \frac{1}{n} \sum_{i=1}^n X_i^3$ ,  $\bar{m}_{4,n} = \frac{1}{n} \sum_{i=1}^n (X_i^4 - 3)$ . Then by the (multivariate) CLT,

$$\sqrt{n} \begin{bmatrix} \bar{m}_{3,n} \\ \bar{m}_{4,n} \end{bmatrix} \xrightarrow{d} N(0, \Sigma),$$

where

$$\Sigma = \begin{bmatrix} \mathbb{E}[X^6] & \mathbb{E}[X^3(X^4 - 3)] \\ \mathbb{E}[X^3(X^4 - 3)] & \mathbb{E}[(X^4 - 3)^2] \end{bmatrix} = \begin{bmatrix} 15 & 0 \\ 0 & 96 \end{bmatrix}.$$

Use this to devise a  $\chi^2$ -test statistic to assess whether a sequence of observations  $(X_1, \dots, X_n)$  are i.i.d. standard Normals.

**Solution.** If we normalize by the appropriate constants  $Z_{1,n} = \frac{\sqrt{n} \bar{m}_{3,n}}{\sqrt{15}}$ ,  $Z_{2,n} = \frac{\sqrt{n} \bar{m}_{4,n}}{\sqrt{96}}$ , then

$$(Z_{1,n}, Z_{2,n}) \xrightarrow{d} (Z_1, Z_2), \quad (Z_1, Z_2) \sim N(0, I)$$

where  $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ , so  $J_n = Z_{1,n}^2 + Z_{2,n}^2$  tends to a  $\chi^2$ -random variable with  $\nu = 2$  df.

**Remark 0.3** This is a simpler version of the well known **Jarque-Bera test** for normality, which uses  $J = \frac{n}{6}(S^2 + \frac{1}{4}(K - 3)^2)$  as the test statistic, where  $S$  is the sample skewness and  $K$  is the sample kurtosis. This test can be computed in Python using `stats.jarque_bera(Z1)`.

**11.** Consider a general stochastic volatility model  $dS_t = S_t \sqrt{V_t} dB_t$ . Then the VIX volatility index at time  $t$  satisfies

$$\text{VIX}_t^2 = \frac{1}{\Delta} \mathbb{E} \left( \int_t^{t+\Delta} V_u du | \mathcal{F}_t^W \right) = \frac{1}{\Delta} \int_t^{t+\Delta} \mathbb{E}(V_u | \mathcal{F}_t^W) du.$$

Now assume  $V$  satisfies the rough CEV-Volterra model:

$$V_t = V_0 + \nu \int_0^t (t-s)^{H-\frac{1}{2}} V_s^p dW_s$$

with  $H \in (0, \frac{1}{2})$ ,  $\nu, V_0, p > 0$  and  $\mathbb{E}(W_t B_t) = \rho t$  with  $\rho \in [-1, 0]$ . Compute an explicit expression for  $\text{VIX}_t^2$  under this model. **Solution.**

$$\begin{aligned} \xi_t(u) &:= \mathbb{E}(V_u | \mathcal{F}_t^W) = V_0 + \nu \int_0^t (u-s)^{H-\frac{1}{2}} V_s^p dW_s \\ \Rightarrow \text{VIX}_t^2 &= V_0 + \frac{\nu}{\Delta} \int_t^{t+\Delta} \int_0^t (u-s)^{H-\frac{1}{2}} V_s^p dW_s du = V_0 + \frac{\nu}{\Delta} \int_0^t \left( \int_t^{t+\Delta} (u-s)^{H-\frac{1}{2}} du \right) V_s^p dW_s \\ &= V_0 + \frac{\nu}{\Delta(\frac{1}{2} + H)} \int_0^t ((t+\Delta-s)^{\frac{1}{2}+H} - (t-s)^{\frac{1}{2}+H}) V_s^p dW_s \end{aligned}$$

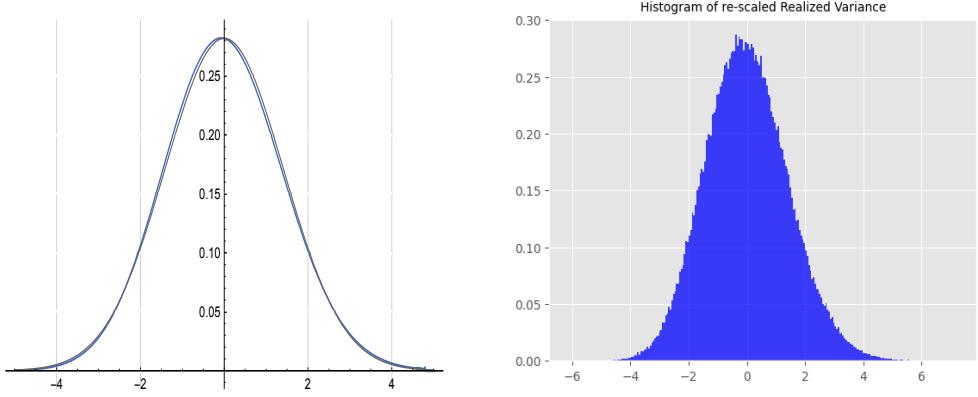

Figure 1: On the left we have plotted the exact density of  $\sqrt{n}(\sum_{i=1}^n (\Delta W_i)^2 - t)$  (in blue, computed using a  $\chi^2$  density) with  $t = 1$  and  $n = 800$ , versus the density of an  $N(0, 2)$  random variable (grey), and we see they are almost identical, as the CLT shows above. On the right we have plotted a histogram of  $\sqrt{n}(\sum_{i=1}^n (\Delta W_i)^2 - t)$  with 250,000 Brownian paths and  $n = 200$  time steps which again tends to an  $N(0, 2)$  distribution as  $n \rightarrow \infty$ , and the sample variance here came out to 2.0111, i.e. close to 2.

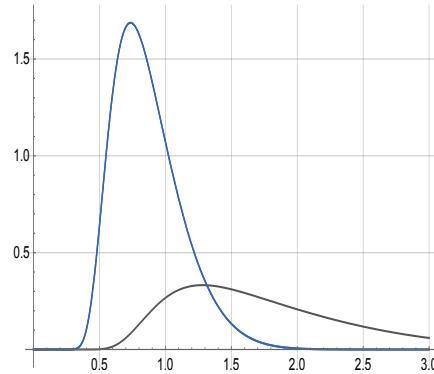

Figure 2: Density of the two-sided maximum for standard Brownian motion from Hwk 4 q2 (grey) and the Brownian bridge in q8 here (blue) on  $[0, 1]$ .

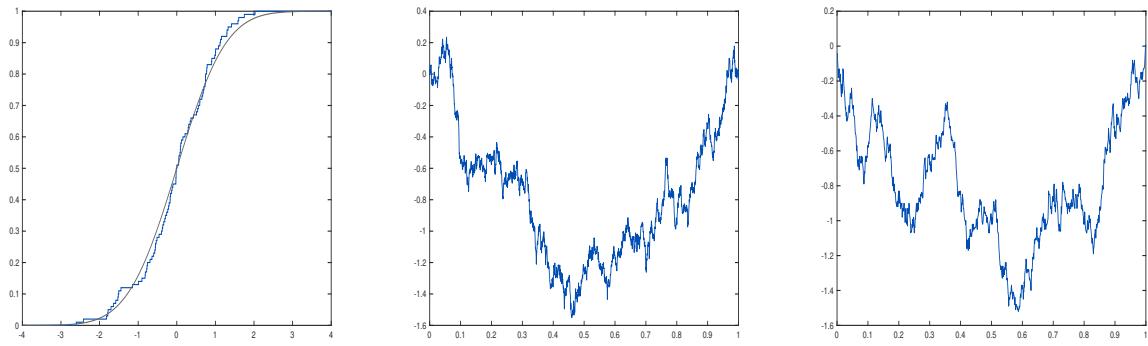

Figure 3: On the left we see the empirical cdf of 100 i.i.d standard Normals (in blue) and the exact cdf of a standard Normal (in grey). In the middle we see an exact Monte Carlo simulation of a Brownian bridge. On the right we see a simulation of  $\sqrt{n}(F_n(F^{-1}(u)) - u)$  for  $n = 10000$  from  $u = .001$  to  $.999$ , which is close to a true Brownian bridge by the result discussed above
