A simplified unified propagator model for signed/unsigned order flow, concave price impact and rough volatility

Similar to Theorem 3.1 in [MORS26], we consider a hyper-rough Heston process $(F_t^+)_{t\geq 0}$ which satisfies

$$F_t^+ \;=\; g(t) \;+\; \int_0^t f(t-s)B_{F_s^+}ds$$

where B is a standard Brownian motion with $B_0 = 0$ and $f(t) = e^{-\theta t}t^{H-\frac{1}{2}}$ is the usual Gamma kernel with $H \in (-\frac{1}{2}, \frac{1}{2})$, $\theta > 0$ so $f \in L^1$ and we assume $g \in C^1$, and we know that F_t^+ is a.s. $2\alpha - \varepsilon \wedge 1$-Hölder continuous where $\alpha = H + \frac{1}{2}$ [1]; F^+ is an increasing process which is non-differentiable if $H \leq 0$. Then if $h * f \equiv 1$, we see that

$$
\int_0^t h(t-s)(F_s^+ - g(s))ds \;=\; \int_0^t h(t-s)\int_0^s f(s-u)B_{F_u^+}du\,ds \;=\; \int_0^t \int_u^t h(t-s)f(s-u)ds\,B_{F_u^+}du
$$
$$
= \int_0^t \int_0^{t-u} h(t-s-u)f(s)ds\,B_{F_u^+}du
$$
$$
= \int_0^t (h*f)(t-u)B_{F_u^+}du \;=\; \int_0^t B_{F_u^+}du
$$

where Fubini is justified since $F_t^+ < \infty$ a.s. for finite t and B is a.s. continuous, and thus

$$\frac{d}{dt}\int_0^t h(t-s)(F_s^+ - g(s))ds \;=\; B_{F_t^+}.$$

Taking Laplace transforms, the condition $h * f \equiv 1$ becomes $\hat{f}(\lambda)\hat{h}(\lambda) = \frac{1}{\lambda}$, from which we find that

$$h(t) \;=\; \frac{1}{\Gamma(\frac{1}{2}+H)}\theta^{\frac{1}{2}+H}\left(1 - \frac{\Gamma(-\frac{1}{2}-H, t\theta)}{\Gamma(-\frac{1}{2}-H)}\right)$$

where $\Gamma(a, z) = \int_z^\infty s^{a-1}e^{-s}ds$ is the incomplete Gamma function, and in particular $h(t) = O(t^{-H-\frac{1}{2}})$ as $t \to 0$.

Again following [MORS26], we now assume the *signed order flow* for an asset is

$$V_t \;=\; F_t^+ - F_t^- \tag{1}$$

where $F_t^- = g(t) + \int_0^t f(t-s)W_{F_s^-}ds$ and W is another Brownian motion independent of B (so F^- is an i.i.d. copy of F^+). Then we see that

$$\frac{d}{dt}\int_0^t h(t-s)V_s ds \;=\; B_{F_t^+} - W_{F_t^-}$$

since the g terms cancel, and for $0 \leq t \leq u$

$$\mathbb{E}(F_u^+|\mathcal{F}_{F_t^+}^B) \;=\; g(u) + \mathbb{E}\left(\int_0^u f(u-s)B_{F_s^+}ds\Big|\mathcal{F}_{F_t^+}^B\right) \;=\; g(u) + \int_0^t f(u-s)B_{F_s^+}ds + B_{F_t^+}\int_t^u f(u-s)ds$$

(and similarly for $\mathbb{E}(F_u^-|\mathcal{F}_{F_t^-}^W)$), where we have used that $(B_{F_t^+})_{t\geq 0}$ is a $\mathcal{G}_t^+$−martingale (give reference), where $\mathcal{G}_t^+ = \mathcal{F}_{F_t^+}^B$.

Making the usual assumption that the asset price $P_t = \kappa \lim_{u\to\infty}\mathbb{E}(F_u|\mathcal{G}_t)$ where $F_t = F_t^+ - F_t^-$ and $\mathcal{G}_t = \sigma(\mathcal{G}_t^+, \mathcal{G}_t^-)$ with $\mathcal{G}_t^- = \mathcal{F}_{F_t^-}^W$ (for some $\kappa > 0$) [2], we find that $f(u-s) \to 0$ as $u \to \infty$ since $\theta > 0$, but $\lim_{u\to\infty}\int_t^u f(u-s)ds = c_{H,\theta}$ where $c_{H,\theta} = \theta^{-\frac{1}{2}-H}\Gamma(\frac{1}{2}+H)$, so

$$P_t \;=\; \kappa \lim_{u\to\infty}\mathbb{E}(F_u^+ - F_u^-\,|\,\sigma(\mathcal{F}_{F_t^+}^B, \mathcal{F}_{F_t^-}^W)) \;=\; \kappa\,c_{H,\theta}(B_{F_t^+} - W_{F_t^-})$$

i.e. P is the difference of two i.i.d. hyper-rough Heston models (each with correlation $\rho = 1$ since each process only has one driving Brownian motion), and

$$P_t \;=\; \kappa\,c_{H,\theta}\frac{d}{dt}\int_0^t h(t-s)V_s ds$$

---

[1] we can simulate this process using the Monte Carlo scheme in [AA25] via Normal Inverse Gaussian variates

[2] note we are assuming $P_0 = 0$ without loss of generality since we can easily add a P_0 term

which is a weak formulation of the usual Propagator model, and the *unsigned* order flow is $U_t = F_t^+ + F_t^-$. In particular, the *market impact function* of an exogenous metaorder executed at constant trading speed 1 up time t_0 is given by

$$MI(t) \quad = \quad \frac{d}{dt}\int_0^t h(t-s)sds \quad = \quad \frac{\theta^{-\frac{1}{2}+H}(t\theta\Gamma(-\alpha_+) - t\theta\Gamma(-\alpha_+, t\theta) - \Gamma(\alpha_-, 0) + \Gamma(\alpha_-, t\theta))}{\Gamma(-\alpha_+)\Gamma(\alpha_+)}$$

for $0 \le t \le t_0$ (with $\alpha_\pm = \frac{1}{2} \pm H$) which is $O(t^{\frac{1}{2}-H})$ as $t \to 0$ and globally concave in t for $H \in (-\frac{1}{2}, \frac{1}{2})$, consistent with empirical evidence (note the usual square-root impact law corresponds to $H = 0$ here), and we can show that the asymptotic (i.e. permanent) impact as $t \to \infty$ (given no trading after t_0) is

$$\frac{t_0\theta^\alpha}{\Gamma(\alpha)}$$

(this is the asymptotic grey line in the plot below). Recall from above that F_t^+ has Hölder regularity $(2\alpha - \varepsilon) \wedge 1$, and empirical evidence in [MORS26] suggests $H \in (-\frac{1}{4}, 0)$, so $2\alpha \in (\frac{1}{2}, 1)$.

Figure 1: Price impact of an exogenous metaorder executed at constant trading speed 1 over $[0,1]$ with $H = -\frac{2}{10}$, $\theta = \frac{1}{10}$ and $\kappa = 1$. The blue line asymptotes to the horizontal grey line as $t \to \infty$ which represents the permanent price impact.
